NODE-SCREENING TESTS FOR L0-PENALIZED LEAST-SQUARES PROBLEM WITH SUPPLEMENTARY MATERIAL

Théo Guyard* Cédric Herzet[†] Clément Elvira[‡]

ABSTRACT

We present a novel screening methodology to safely discard irrelevant nodes within a generic branch-and-bound (BnB) algorithm solving the ℓ_0 -penalized least-squares problem. Our contribution is a set of two simple tests detecting nodes that cannot yield optimal solutions of the problem. We provide a nesting property for these tests allowing to avoid entire branches of the BnB tree that need not be processed by the algorithm, thus reducing the overall solution time. Our work leverages the concept of safe screening, well known for sparsity-inducing convex problems, and some recent advances in this field for ℓ_0 -penalized regression problems.

Index Terms— Sparse approximation, Mixed-integer problems, Branch-and-bound, Safe screening.

1. INTRODUCTION

Finding a sparse representation is a fundamental problem in the field of statistics, machine learning and inverse problems. It consists in decomposing some input vector $\mathbf{y} \in \mathbb{R}^m$ as a linear combination of a few columns (dubbed *atoms*) of a dictionary $\mathbf{A} \in \mathbb{R}^{m \times n}$. This task can be addressed by solving

$$\min_{\mathbf{x} \in \mathbb{R}^n} \ \frac{1}{2} \|\mathbf{y} - \mathbf{A}\mathbf{x}\|_2^2 + \lambda \|\mathbf{x}\|_0 \tag{1}$$

where $\|\mathbf{x}\|_0$ counts the number of nonzero entries in \mathbf{x} and $\lambda > 0$ is a tuning parameter. Unfortunately, problem (1) has proven to be NP-hard in the general case [1, Th. 3]. This has led researchers to develop sub-optimal procedures to approximate its solution and address large-scale problems. Among the most popular, one may mention greedy algorithms and methodologies based on convex relaxation, see *e.g.* [2, Sec. 3.2 and Ch. 4].

Sub-optimal procedures are however only guaranteed to solve (1) under restrictive conditions that are rarely met when dealing with highly-correlated dictionaries. On the other

hand, there has been recently a surge of interest for the devise of methods that solve (1), see [3–6] to name a few. Many approaches leverage the fact that finding

$$p^{\star} = \min_{\mathbf{x} \in \mathbb{R}^n} \frac{1}{2} \|\mathbf{y} - \mathbf{A}\mathbf{x}\|_2^2 + \lambda \|\mathbf{x}\|_0 \text{ s.t. } \|\mathbf{x}\|_{\infty} \le M \quad (P)$$

is equivalent to solve (1), provided that M is chosen large enough. Interestingly, (P) can be reformulated as a mixed-integer program (MIP) by introducing binary variables encoding the nullity of the entries of \mathbf{x} . See, e.g., [4]. Besides, (P) has shown to be solvable for moderate-size problems by both commercial solvers [7] and tailored BnB algorithms [6].

In a recent paper, Atamtürk and Gómez have extended the notion of safe screening introduced by El Ghaoui $et\ al.$ in [8] from sparsity-promoting convex problems to non-convex ℓ_0 -penalized problems. In particular, they have introduced a new methodology that allows to detect (some of) the positions of zero and non-zero entries in the minimizers of a particular ℓ_0 -penalized problem [9]. Their methodology is used as a pre-processing step of any algorithmic procedure and allows to reduce the problem dimensionality. This procedure takes the form of a test that can be applied to each entry of any global minimizer of the considered problem.

In this paper, we make one step forward in the development of numerical methods addressing large-scale ℓ_0 -penalized problems by proposing *node-screening* rules that can be implemented *within* any BnB algorithm. in contrast to [9], our method is tailored for (P) and can be applied at any time *during* the optimization process. Quite notably, we make also use of a nesting property of our tests to efficiently apply them at each node of the exploration tree in an efficient fashion and with marginal cost. Interestingly, our method can be seen as a generalization to (P) of the *reduced-cost fixing* idea that only applies for MIPs with a *linear* objective [10, 11].

Our exposition is organized as follows. In Sec. 3, we describe a BnB algorithm tailored to solve (P). Sec. 4 presents our new node-screening tests and explains how to implement them efficiently within the BnB process. Finally in Sec. 5, we assess the performance of our method in different experimental setups. All the proofs are postponed to Appendix A.

2. NOTATIONS

We use the following notational conventions throughout the paper. Boldface uppercase $(e.g., \mathbf{A})$ and lowercase $(e.g., \mathbf{x})$ letters respectively represent matrices and vectors. $\mathbf{0}$ denotes the all-zeros vector. Since the dimension will usually be clear from the context, it is omitted in the notation. The ith column of a matrix \mathbf{A} is denoted \mathbf{a}_i . Similarly, the ith entry of a vector \mathbf{x} is denoted x_i . Calligraphic letters $(e.g., \mathcal{S})$ are used to denote sets and the notation $|\cdot|$ refers to their cardinality. If $\mathcal{S} \subseteq \{1,\ldots,n\}$ and $\mathbf{x} \in \mathbb{R}^n$, $\mathbf{x}_{\mathcal{S}}$ denotes to the restriction of \mathbf{x} to its elements indexed by \mathcal{S} . Similarly, $\mathbf{A}_{\mathcal{S}}$ corresponds to the restriction of \mathbf{A} to its columns indexed by \mathcal{S} .

3. BRANCH-AND-BOUND PROCEDURES

Branch-and-bound procedures refer to an algorithmic solution to address MIPs, among others [12]. It consists in implicitly enumerating all feasible solutions and applying pruning rules to discard irrelevant candidates. When particularized to problem (P), it can be interpreted as a search tree where a new decision regarding the nullity of an entry of the variable x is taken at each node as illustrated in Fig. 1a. Formally, we define a node as a triplet $\nu = (S_0, S_1, \bar{S})$ where : i) S_0 and S_1 contain the indices of the entries of x which are forced to be zero and non-zero, respectively; ii) \bar{S} gathers all the entries of x for which no decision has been taken at this stage of the decision tree. In the sequel, we say that $\nu' = (S_0', S_1', \bar{S}')$ is a sub-node of $\nu = (S_0, S_1, \bar{S})$, written $\nu' \subset \nu$, if $S_0 \subset S_0'$ and $S_1 \subset S_1'$. We also denote $\nu \cup \{x_i = 0\}$ and $\nu \cup \{x_i \neq 0\}$ the two direct sub-nodes of ν where index i has been swapped from \bar{S} to S_0 or S_1 , respectively.

In the BnB tree, each node corresponds to problem (P) with some additional constraints on the variable entries. In particular, let $\nu = (S_0, S_1, \bar{S})$ be a node, then the *subproblem* at node ν can be reformulated as finding

$$p^{\nu} = \min_{\mathbf{x} \in \mathbb{R}^n} \frac{1}{2} \|\mathbf{y} - \mathbf{A}\mathbf{x}\|_2^2 + \lambda \|\mathbf{x}_{\bar{\mathcal{S}}}\|_0 + \lambda |\mathcal{S}_1|$$
s.t. $\|\mathbf{x}\|_{\infty} \leq M$ and $\mathbf{x}_{\mathcal{S}_0} = \mathbf{0}$ (P^{ν})

where the ℓ_0 -penalty of non-zero entries is expressed with respect to the cardinality of \mathcal{S}_1 . Although not presented, entries set to zero can be discarded, along with the corresponding columns of \mathbf{A} , without changing the value of p^{ν} . One also has by construction $p^{\nu} \geq p^{\star}$ since the minimizers of (P^{ν}) are also feasible for (P). If the new constraints match to the configuration of one of the minimizers of (P), then (P^{ν}) also yields this global solution to (P). The BnB algorithm reads as follows: starting from node $\nu = (\emptyset, \emptyset, \{1, \ldots, n\})$, the method alternates between processing the current node (bounding step) and selecting a new node (branching step). The algorithm identifies the global minimum in a finite number of steps with

a worst-case complexity equal to an exhaustive search. In practice, its efficiency depends both on the ability to process nodes quickly and on the number of nodes processed. We now review specific choices for these two steps tailored for problem (P).

3.1. Bounding step

When processing node $\nu = (S_0, S_1, \bar{S})$, problem (P^{ν}) is not directly solved but is rather checked against lower and upper bounds to test it it can yield an optimal solution to (P). To do so, we evaluate a *lower bound* on p^{ν} by solving the following relaxation of (P^{ν})

$$\begin{aligned} p_l^{\nu} &= \min_{\mathbf{x} \in \mathbb{R}^n} \frac{1}{2} \|\mathbf{y} - \mathbf{A}\mathbf{x}\|_2^2 + \frac{\lambda}{M} \|\mathbf{x}_{\bar{\mathcal{S}}}\|_1 + \lambda |\mathcal{S}_1| \\ &\text{s.t. } \|\mathbf{x}\|_{\infty} \leq M \text{ and } \mathbf{x}_{\mathcal{S}_0} = \mathbf{0} \end{aligned}$$
 (P_l^{ν})

where the ℓ_0 -penalty of $\mathbf{x}_{\bar{\mathcal{S}}}$ has been replaced by the ℓ_1 -norm, that is the sum in absolute value of the entries. Interestingly, (P_l^{ν}) is a constrained LASSO problem [13] and can thus be solved in polynomial time by using one of the many methods suitable for this class of problems [14, 15].

During the BnB, we keep track of the best known objective value p_u of (P), which is an upper bound on p^* . If $p_l^{\nu} > p_u$, then node ν is pruned from the tree as it cannot yield an optimal solution, nor its sub-nodes. Otherwise, we construct some feasible solution of (P^{ν}) to obtain an upper bound p_u^{ν} on p^* and the best known upper bound is updated as $p_u \leftarrow \min(p_u, p_u^{\nu})$. During the BnB process, p_u converges toward p^* and relaxation are strengthened as new variables are fixed, allowing to prune nodes more efficiently.

3.2. Branching step

If node $\nu=(S_0,S_1,\bar{S})$ has not been pruned during the bounding step, the tree exploration goes on. An index $i\in\bar{S}$ is selected according to some *variable selection rule* and two direct sub-nodes are created below ν by imposing either " $x_i=0$ " or " $x_i\neq 0$ ". Finally, when all nodes have been explored or pruned, the BnB algorithm stops and any candidate yielding the best upper bound p_u is a minimizer of (P).

4. NODE-SCREENING TESTS

In this section, we present our new node-screening tests. They aim at identifying, with a marginal cost, nodes of the search tree that *cannot* yield a global minimum of (P).

4.1. Dual properties

The crux of our procedure is a connection between the Fenchel dual problem of (P_l^{ν}) at two consecutive nodes. Prior to expose these results, let use define for all $\mathbf{u} \in \mathbb{R}^m$

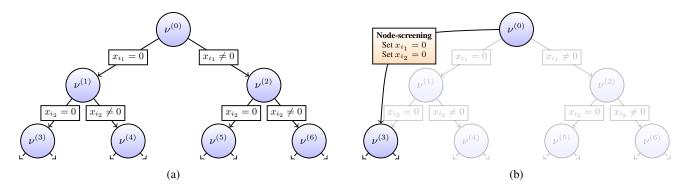

Fig. 1: First nodes of the BnB tree. The root node $\nu^{(0)}$ corresponds to problem (P) and each sub-node corresponds to a subproblem (P^{ν}) with different fixed variables. (a) Standard implementation of a BnB where all nodes are processed. (b) Impact of applying node-screening tests on the BnB search tree: at node $\nu^{(0)}$, test (6b) is passed for entries i_1 and i_2 ; one can thus directly switch to the sub-node including constraints " $x_{i_1} = 0$ " and " $x_{i_2} = 0$ ", namely $\nu^{(3)}$. The other nodes are not explored.

and $i \in \{1, ..., n\}$ three families of *pivot values* as

$$\gamma_{i}(\mathbf{u}) \triangleq M \times (|\mathbf{a}_{i}^{\mathrm{T}}\mathbf{u}| - \frac{\lambda}{M})
\gamma_{i}^{0}(\mathbf{u}) \triangleq M \times [|\mathbf{a}_{i}^{\mathrm{T}}\mathbf{u}| - \frac{\lambda}{M}]_{+}
\gamma_{i}^{1}(\mathbf{u}) \triangleq M \times [\frac{\lambda}{M} - |\mathbf{a}_{i}^{\mathrm{T}}\mathbf{u}|]_{+}$$
(2)

where $[x]_{+} \triangleq \max(0, x)$ for all scalars x. We now express the Fenchel dual of (P_I^{ν}) with respect to these quantities.

Proposition 1. The Fenchel dual of (P_I^{ν}) is given by

$$d^{\nu} = \max_{\mathbf{u} \in \mathbb{R}^{m}} D^{\nu}(\mathbf{u}) \triangleq \frac{1}{2} \|\mathbf{y}\|_{2}^{2} - \frac{1}{2} \|\mathbf{y} - \mathbf{u}\|_{2}^{2}$$
$$- \sum_{i \in \bar{\mathcal{S}}} \gamma_{i}^{0}(\mathbf{u}) - \sum_{i \in \mathcal{S}_{1}} \gamma_{i}(\mathbf{u}) \qquad (D^{\nu})$$

and strong duality holds for (P_l^{ν}) - (D^{ν}) , i.e., $p_l^{\nu}=d^{\nu}$. Moreover, if $(\mathbf{x}^*, \mathbf{u}^*)$ is a couple of primal-dual solutions, one has

$$\mathbf{u}^{\star} = \mathbf{v} - \mathbf{A}\mathbf{x}^{\star}.\tag{3}$$

Hence, at a given node ν , the dual objective of (P_l^{ν}) is the sum of a term common to all nodes and some well-chosen pivot values. Interestingly, the dual objective functions between two consecutive nodes only differ from one pivot value as shown by the following result.

Corollary 1. Let $\nu = (S_0, S_1, \bar{S})$ and $i \in \bar{S}$, then $\forall \mathbf{u} \in \mathbb{R}^m$,

$$D^{\nu \cup \{x_i=0\}}(\mathbf{u}) = D^{\nu}(\mathbf{u}) + \gamma_i^0(\mathbf{u})$$
 (4a)

$$D^{\nu \cup \{x_i \neq 0\}}(\mathbf{u}) = D^{\nu}(\mathbf{u}) + \gamma_i^1(\mathbf{u})$$
 (4b)

4.2. Node-screening tests

We now expose our proposed node-screening strategy to identify branches of the tree that provably cannot yield a global minimizer of (P). Let ν be a node and p_u an upper bound of p^* . We have by strong duality between (P_l^{ν}) - (D^{ν}) that $\forall \mathbf{u} \in \mathbb{R}^m$,

$$D^{\nu}(\mathbf{u}) \le d^{\nu} = p_l^{\nu} \le p^{\nu}. \tag{5}$$

Hence, combining (5) with Cor. 1 leads to the next result.

Proposition 2. Let $\ell \in \bar{S}$ be some index. Then, $\forall \mathbf{u} \in \mathbb{R}^m$,

$$D^{\nu}(\mathbf{u}) + \boldsymbol{\gamma}_{\ell}^{0}(\mathbf{u}) > p_{u} \quad \Longrightarrow \quad p^{\nu \cup \{x_{\ell} = 0\}} > p^{\star} \qquad \text{(6a)}$$

$$D^{\nu}(\mathbf{u}) + \boldsymbol{\gamma}_{\ell}^{1}(\mathbf{u}) > p_{u} \quad \Longrightarrow \quad p^{\nu \cup \{x_{\ell} \neq 0\}} > p^{\star} \qquad \text{(6b)}$$

$$D^{\nu}(\mathbf{u}) + \gamma_{\ell}^{1}(\mathbf{u}) > p_{u} \quad \Longrightarrow \quad p^{\nu \cup \{x_{\ell} \neq 0\}} > p^{\star}$$
 (6b)

Stated otherwise, Prop. 2 describes a simple procedure to identify at a given node some sub-nodes that cannot yield an optimal solution of (P). Hence, if (6a) or (6b) passes, the BnB process can avoid safely the corresponding sub-node, as well as the branch starting from it. Moreover, if both (6a) and (6b) pass for a given index, then all branches starting from ν cannot yield an optimal solution and node ν can thus be pruned.

Our proposed procedure differs from the pruning methodology described in Sec. 3 in several aspects. Performing a test only requires the evaluation of a single inner product. They can therefore be implemented at marginal cost compared to the overall cost of the bounding step. Very importantly, they also inherit from the following *nesting property*:

Corollary 2. Let $\nu = (S_0, S_1, \bar{S})$ be a node. Then, if test (6a) or (6b) passes for index $\ell \in \bar{S}$, then it also passes for any subnode $\nu' = (S'_0, S'_1, \bar{S}') \subset \nu$ such that $\ell \notin \bar{S}'$.

In particular, Cor. 2 has the following consequence. Assume that at node ν , the two distinct indexes ℓ and ℓ' pass the test (6a). Then index ℓ' will also pass (6a) at node $\nu \cup \{x_{\ell} \neq \ell\}$ 0}. The same consequence holds for test (6b) and node ν \cup $\{x_{\ell}=0\}$. In other words, if several node-screening tests pass at a given node, one can directly switch to the sub-node that includes all the conclusions from the tests, as illustrated in Fig. 1b.

4.3. Implementation considerations

Implementing node-screening tests described by Prop. 2 requires the knowledge of an upper bound p_u of p^* and a suitable $\mathbf{u} \in \mathbb{R}^m$, i.e., as close as possible to the maximizer of (D^{ν}) . The value of p_u can be obtained at no additional cost since the standard implementation of BnB already requires storing such valid upper bounds of p^{\star} . To obtain a relevant candidate for \mathbf{u} , we suggest the following procedure: assuming the method used to solve (P_l^{ν}) generates a sequence of feasible iterates $\{\mathbf{x}^{(t)}\}_{t\in\mathbb{N}}$ that converges to a global minimizer, we set

$$\forall t \in \mathbb{N}, \quad \mathbf{u}^{(t)} = \mathbf{y} - \mathbf{A}\mathbf{x}^{(t)}. \tag{7}$$

This choice enjoys two desirable properties. First, the sequence $\{\mathbf{u}^{(t)}\}_{t\in\mathbb{N}}$ converges toward a maximizer of (D^{ν}) as a consequence of the optimality condition (3). Second, both $\mathbf{u}^{(t)}$ and $\mathbf{A}^{\mathrm{T}}\mathbf{u}^{(t)}$ are already evaluated by most solvers as they correspond to the residual error and the (negative) gradient of the least-squares term of the objective function, respectively. Thus, the computational cost of evaluating the screening tests at all undecided entries is marginal compared to the cost needed to address (P_l^{ν}) . The latter choice for $\mathbf{u}^{(t)}$ suggests performing node-screening tests *during* the bounding step. Hence, when some entries passes the test, the BnB algorithm immediately switches to the corresponding sub-node, regardless of the stage of the bounding step.

5. NUMERICAL RESULTS

We finally report simulation results illustrating the relevance of the node-screening methodology on two different setups.

5.1. Experimental setups

For each trial, we generate a new realization of dictionary $\mathbf{A} \in \mathbb{R}^{m \times n}$ and observation vector $\mathbf{y} \in \mathbb{R}^m$ as follows. In the Gaussian setup, we set (m, n) = (500, 1000) and the entries of A are i.i.d. realizations of a normal distribution. In the *Toeplitz* setup, we set (m, n) = (500, 300) and the first column of A contains a sample of a sinus-cardinal. The other columns are obtained by shifting the entries in a row-wise fashion so that A inherits from a Teplitz structure. In both setups, the columns are then normalized to one. To obtain y, we first sample a k-sparse vector \mathbf{x}^0 of the appropriate size with uniformly distributed non-zero entries. Each non-zero entry is set to s(1+|a|), where $s \in \{-1, +1\}$ is a random sign and a is a realization of the normal distribution. In our experiment, we chose $k \in \{5, 7, 9\}$. Finally, the observation is constructed as $\mathbf{y} = \mathbf{A}\mathbf{x}^0 + \boldsymbol{\epsilon}$ where the entries of $\boldsymbol{\epsilon}$ are i.i.d. realizations of a centered Gaussian distribution with standard deviation $\sigma = \|\mathbf{A}\mathbf{x}^0\|_2 / \sqrt{10m}$. Such a design leads in average to a SNR of 10 dB [16]. We tune λ statistically as in [17], i.e., by setting $\lambda = 2\sigma^2 \log(n/k - 1)$. Finally, we empirically set $M = 1.5 \times \|\mathbf{A}^{\mathrm{T}}\mathbf{y}\|_{\infty}$ as advised in [6].

We compare three methods that address (P): i) MIP, that uses CPLEX [7], a state-of-the-art commercial MIP solver; ii) BnB, the algorithm presented in [6], which is (up to our knowledge) the fastest BnB algorithm tailored for (P); iii)

BnB+scr which corresponds to BnB enhanced with the node-screening methodology presented in Sec. 4. Note that both BnB and BnB+scr leverage an efficient implementation of the Active-Set algorithm [18, Sec. 16.5] to solve (P_l^{ν}) and a particular variable selection rule for the branching-step.

Experiments are run on a MacOS with an i7 CPU, clocked at 2.2 GHz and with 8Go of RAM. We restrict calculations on a single core to avoid bias due to parallelization capabilities. The Academic Version 20.1 of CPLEX is used and both BnB and BnB+scr are implemented in Julia v1.5 [19]. Results are averaged over 100 instances of problem (*P*).

5.2. Method comparison

Table 1 compares the average number of nodes treated (*i.e.*, the number of relaxations (P_l^{ν}) solved) and the solution time for the three methods and all simulation setups. One observes that BnB+scr outperforms the two other methods on all scenarii and all figure-of-merits. We also note that compared to BnB, the reduction in the solution time is more significant than the reduction in the number of nodes processed. A thorough examination of our results indicates that BnB+scr tends to reach faster nodes where entries are set to zero compared to BnB and MIP thanks to node-screening tests. Hence, the dimensionality of the reduced problems that need to be solved is lower than the two other methods, thus enabling computational savings.

As a final remark, we mention that MIP relies on an efficient C++ implementation while BnB and BnB+scr are implemented in Julia. There is therefore room for improvement in the comparison with MIP.

6. CONCLUSION

In this paper, we presented a novel node-screening methodology aiming at accelerating the resolution of the ℓ_0 -penalized least-squares problem with a branch-and-bound solver. Our contribution leverages a nesting property between the relaxed dual objective functions at two consecutive nodes. Our method leads to significant improvements in terms of node

explored and resolution time on two simulated datasets. Future works include to extend the relationship between distant nodes rather than only consecutive nodes, thus leading to potentially more computational savings.

A. PROOFS

This appendix gathers the proofs of the results derived in Sec. 4. We refer to [6] for proofs regarding Sec. 3.

A.1. Proof of Prop. 1

Our proof of Prop. 1 leverages the Fenchel conjugate of a function f and denoted f^* . In particular, we first state the following technical lemma whose proof is postponed to the end of the section

Lemma 1. Define for all $\mathbf{z} \in \mathbb{R}^m$ and $\mathbf{x} \in \mathbb{R}^n$

$$f_1(\mathbf{z}) \triangleq \frac{1}{2} \|\mathbf{y} - \mathbf{z}\|_2^2 + \varepsilon \tag{8a}$$

$$f_2(\mathbf{x}) \triangleq \frac{\lambda}{M} \|\mathbf{x}_{\mathcal{S}}\|_1 + \eta_{\{\mathbf{x}': \ \mathbf{x}'_{\mathbf{c}'} = \mathbf{0}\}}(\mathbf{x}) + \eta_{\mathcal{B}_{\infty}(M)}(\mathbf{x}) \quad (8b)$$

Then, for all $\mathbf{u} \in \mathbb{R}^m$ and $\mathbf{v} \in \mathbb{R}^n$

$$f_1^*(\mathbf{u}) = \frac{1}{2}(\|\mathbf{y} + \mathbf{u}\|_2^2 - \|\mathbf{y}\|_2^2) - \varepsilon$$
 (9a)

$$f_2^*(\mathbf{v}) = \sum_{i \in \mathcal{S}} M[|v_i| - \frac{\lambda}{M}]_+ + M \|\mathbf{v}_{\mathcal{S}''}\|_1.$$
 (9b)

In the latter result, ε is a scalar, (S, S', S'') is a partition of $\{1, \ldots, n\}$, $\mathcal{B}_{\infty}(M)$ denotes the ℓ_{∞} -ball of \mathbb{R}^n centered at $\mathbf{0}$ with radius M, $\eta_{\mathcal{A}}$ denotes the indicator function of set $\mathcal{A} \subseteq \mathbb{R}^n$ defined for all $\mathbf{x} \in \mathbb{R}^n$ by $\eta_{\mathcal{A}}(\mathbf{x}) = 0$ if $\mathbf{x} \in \mathcal{A}$ and $+\infty$ otherwise.

We now use Lem. 1 to prove : a) the formulation of the dual problem (D^{ν}) , b) the strong-duality relation linking (P_l^{ν}) - (D^{ν}) and c) the relation (1). In the sequel, we let $\nu=(\mathcal{S}_0,\mathcal{S}_1,\bar{\mathcal{S}})$ be a given node.

a) **Dual problem** (D^{ν}) . Using the functions defined in Lem. 1 with $\varepsilon = \lambda |\mathcal{S}_1|$, $\mathcal{S} = \bar{\mathcal{S}}$, $\mathcal{S}' = \mathcal{S}_0$ and $\mathcal{S}'' = \mathcal{S}_1$, the relaxed problem (P_l^{ν}) can be rewritten as

$$\min_{\mathbf{x} \in \mathbb{R}^n} f_1(\mathbf{A}\mathbf{x}) + f_2(\mathbf{x}). \tag{10}$$

Then, the Fenchel dual of (10) is given by $[20, Definition 15.19]^1$

$$\max_{\mathbf{u} \in \mathbb{R}^m} -f_1^*(-\mathbf{u}) - f_2^*(\mathbf{A}^{\mathrm{T}}\mathbf{u}). \tag{11}$$

One concludes the proof by seeing that for all $\mathbf{u} \in \mathbb{R}^m$

$$\begin{split} f_2^*(\mathbf{A}^{\mathrm{T}}\mathbf{u}) - \varepsilon &= \sum_{i \in \bar{\mathcal{S}}} \gamma_i^0(\mathbf{u}) + M \|\mathbf{A}_{\mathcal{S}_1}^{\mathrm{T}}\mathbf{u}\|_1 - \frac{M}{M} \lambda |\mathcal{S}_1| \\ &= \sum_{i \in \bar{\mathcal{S}}} \gamma_i^0(\mathbf{u}) + \sum_{i \in \mathcal{S}_1} \gamma_i(\mathbf{u}). \end{split}$$

- **b)** Strong duality. Strong duality holds as a consequence of [20, Proposition 15.24]. More particularly, one easily verifies that the condition in item vii) is fulfilled since the functions f_1 and f_2 are proper and continuous.
- c) **Relation** (1). Let $(\mathbf{x}^{\nu}, \mathbf{u}^{\nu})$ be a couple of primal-dual solution of (P_l^{ν}) - (D^{ν}) . Since strong duality holds, we have by item ii) of [20, Theorem 19.1] that²

$$-\mathbf{u}^{\nu} \in \partial f_1(\mathbf{A}\mathbf{x}^{\nu}) \tag{12}$$

where $\partial f_1(\mathbf{A}\mathbf{x}^{\nu})$ denotes the sub-differential of f_1 evaluated at $\mathbf{A}\mathbf{x}^{\nu}$. One finally obtains (1) by noticing that f_1 is differentiable at $\mathbf{A}\mathbf{x}^{\nu}$ so that the sub-differential reduces to the singleton $\{\nabla f_1(\mathbf{A}\mathbf{x}^{\nu})\}$.

A.2. Proof of Lem. 1.

The Fenchel conjugate of f_1 evaluated at $\mathbf{u} \in \mathbb{R}^m$ is defined as

$$f_1^*(\mathbf{u}) = \max_{\mathbf{z} \in \mathbb{R}^m} \mathbf{u}^{\mathrm{T}} \mathbf{z} - f_1(\mathbf{z}). \tag{13}$$

One easily sees that (13) is an unconstrained concave optimization problem whose objective function is differentiable. We then obtain (8a) by noticing that the maximum is attained at $\mathbf{z}^* = \mathbf{y} + \mathbf{u}$.

Let $\mathbf{v} \in \mathbb{R}^n$. By definition of f_2^* and using the fact that $f_2(\mathbf{x}) = +\infty$ for all $\mathbf{x} \in \mathbb{R}^n$ such that $\mathbf{x}_{S'} \neq \mathbf{0}$, We have

$$\begin{split} f_2^*(\mathbf{v}) &= \max_{\left\{\mathbf{x} \in \mathbb{R}^n : \|\mathbf{x}\|_{\infty} \leq M\right\}} \mathbf{v}^{\mathrm{T}} \mathbf{x} - \frac{\lambda}{M} \|\mathbf{x}_{\mathcal{S}}\|_1 \\ &= \sum_{i \in \mathcal{S}} \max_{\left\{x \in \mathbb{R} : |x| \leq M\right\}} v_i x_i - \frac{\lambda}{M} |x_i| \\ &+ \max_{\left\{\mathbf{x}_{\mathcal{S}''} \in \mathbb{R}^{|\mathcal{S}''|} : \|\mathbf{x}_{\mathcal{S}''}\|_{\infty} \leq M\right\}} \mathbf{v}_{\mathcal{S}''}^{\mathrm{T}} \mathbf{x}_{\mathcal{S}''}. \end{split}$$

where the optimization problem can be split since it is linear and S, S'' have non empty intersection by definition. Let $i \in S$ and consider the problem

$$x_i^{\star} \in \operatorname{argmax}_{\{x \in \mathbb{R}: |x| \le M\}} v_i x_i - \frac{\lambda}{M} |x_i|.$$
 (14)

We let the reader check that x_i^{\star} defined by

$$x_i^{\star} = \begin{cases} 0 & \text{if } |v_i| - \frac{\lambda}{M} \le 0\\ \text{sign}(v_i)M & \text{otherwise} \end{cases}$$
 (15)

verifies

$$\forall x \in [-M, +M] \quad (v_i - \frac{\lambda}{M}g)(x - x_i^*) \le 0 \tag{16}$$

¹Note that, unlike [20, Definition 15.19], we use the formulation of the dual problem that involves a maximization problem.

²Again, we note that (12) involves the opposite of \mathbf{u}^{ν} since the authors consider the reformulation of the dual as a minimization problem.

where $g \in \partial |x_i^*|$. Hence it is a maximizer of (14). One finally expresses the maximum as a sum of pivot values by injecting the value of x_i^* in the objective function.

Second, see that

$$\begin{aligned} \max_{\left\{\mathbf{x}_{\mathcal{S}^{\prime\prime}} \in \mathbb{R}^{|\mathcal{S}^{\prime\prime}|} : \left\|\mathbf{x}_{\mathcal{S}^{\prime\prime}}\right\|_{\infty} \leq M\right\}} \mathbf{v}_{\mathcal{S}^{\prime\prime}}^{\mathrm{T}} \mathbf{x}_{\mathcal{S}^{\prime\prime}} \\ &= M \times \max_{\left\{\mathbf{x}_{\mathcal{S}^{\prime\prime}} \in \mathbb{R}^{|\mathcal{S}^{\prime\prime}|} : \left\|\mathbf{x}_{\mathcal{S}^{\prime\prime}}\right\|_{\infty} \leq 1\right\}} \mathbf{v}_{\mathcal{S}^{\prime\prime}}^{\mathrm{T}} \mathbf{x}_{\mathcal{S}^{\prime\prime}} \\ &= M \|\mathbf{v}_{\mathcal{S}^{\prime\prime}}\|_{1} \end{aligned}$$

where the last equality holds since one recognizes the Fenchel dual of the indicator function of the unit-ball with respect to the ℓ_{∞} -norm [20, item iv) in Example 13.3] in the penultimate line.

A.3. Proof of Cor. 1

Let $\nu = (S_0, S_1, \bar{S})$ be a node and i be some element of \bar{S} such that $\nu \cup \{x_i = 0\}$ defines a child node. Using (D^{ν}) , we have for all $\mathbf{u} \in \mathbb{R}^m$

$$\begin{split} \mathbf{D}^{\nu \cup \{x_i = 0\}}(\mathbf{u}) - \mathbf{D}^{\nu}(\mathbf{u}) &= \sum_{i' \in \bar{\mathcal{S}}} \gamma_{i'}^0(\mathbf{u}) - \sum_{i' \in \bar{\mathcal{S}} \setminus \{i\}} \gamma_{i'}^0(\mathbf{u}) \\ &= \gamma_i^0(\mathbf{u}). \end{split}$$

Similar calculations lead for all $\mathbf{u} \in \mathbb{R}^m$ to

$$D^{\nu \cup \{x_i \neq 0\}}(\mathbf{u}) - D^{\nu}(\mathbf{u}) = \gamma_i^0(\mathbf{u}) - \gamma_i(\mathbf{u})$$
$$= \gamma_i^1(\mathbf{u})$$

where the last line uses the relation $[u]_+ - [-u]_+ = u$ that hold for all scalar u.

A.4. Proof of Cor. 2

Let $\nu=(\mathcal{S}_0,\mathcal{S}_1,\bar{\mathcal{S}})$ be a node. We first state the following lemma which can easily be proved by induction using (4a) and (4b).

Lemma 2. Let $\nu' = (S'_0, S'_1, \bar{S}')$ be a child node of ν . Then, for all $\mathbf{u} \in \mathbb{R}^m$

$$D^{\nu'}(\mathbf{u}) = D^{\nu}(\mathbf{u}) + \sum_{i \in \mathcal{S}_0' \setminus \mathcal{S}_0} \gamma_i^0(\mathbf{u}) + \sum_{i \in \mathcal{S}_1' \setminus \mathcal{S}_0} \gamma_i^1(\mathbf{u}). \quad (17)$$

We now prove Cor. 2. Let $\ell \in \bar{S}$ be some index such that test (6a) or (6b) passes at node ν . To easier our exposition, we only prove the result for test (6a) as the same rationale can be used for test (6b).

Hence, assume that test (6a) passes for index ℓ at node ν , *i.e.*, that

$$D^{\nu}(\mathbf{u}) + \gamma_{\ell}^{1}(\mathbf{u}) > p_{u}. \tag{18}$$

Let $\nu' = (S_0', S_1', \bar{S}')$ be a child node of ν such that $\ell \notin \bar{S}'$. Using Lem. 2, we have

$$D^{\nu'}(\mathbf{u}) = D^{\nu}(\mathbf{u}) + \sum_{i \in \mathcal{S}_0' \setminus \mathcal{S}_0} \gamma_i^0(\mathbf{u}) + \sum_{i \in \mathcal{S}_1' \setminus \mathcal{S}_0} \gamma_i^1(\mathbf{u}). \quad (19)$$

Since the pivots values $\{\gamma_i^0(\mathbf{u})\}_{i=1}^n \{\gamma_i^1(\mathbf{u})\}_{i=1}^n$ are all nonnegative by construction, we necessarily have $D^{\nu'}(\mathbf{u}) \geq D^{\nu}(\mathbf{u})$. Hence the test (6a) also passes for index ℓ at node ν' .
